ABSTRACT
Solar Energy is an upcoming solution to one of the world’s biggest problems: The lack of clean energy. This research paper focuses on understanding the factors that influence the perception of Indian respondents toward solar energy, in order to fill in the gap in the data regarding how basic socio-economic factors such as age, education, and income level can influence one’s thoughts towards solar energy. This is a mixed-method study that aims to draw relations and trends between the above-stated factors and the perceptions of the respondents. It was concluded after analyzing a dataset of 140 respondents (middle Class and upper-class respondents from Metropolitan cities of Delhi, Mumbai, Bangalore, and Chennai, and Lower Class respondents from Kishangargh Village, New Delhi), from different income and education levels, that there was a positive relationship between education level and awareness as well as income and likelihood of adoption. Other factors such as age and gender of the respondents have also been taken into account in the study. The age of the respondents had a positive relationship with their perception of solar energy, Whereas gender showed no relation with the perception of the respondents.

Keywords: Solar energy; solar technology; sustainability; consumer behavior; socioeconomic background; electricity; sustainability goals; income level; education and awareness.

1. INTRODUCTION
The amount of sunlight that strikes the earth’s surface in an hour and a half is enough to handle the entire world’s energy consumption for a full year [1]. Solar technologies convert sunlight into electrical energy either through photovoltaic panels or through mirrors that concentrate solar
radiation. This energy can be used to generate electricity or be stored in batteries or thermal storage [1]. In recent years countries across the world have started to shift towards this cleaner method of energy.

According to data from the International Energy Renewable Agency, at the end of 2020, the worldwide capacity of solar PV has increased to 714 GW and upward trends in solar have been observed since 2004 [2]. Solar energy continues to lead the percentage capacity expansion with a 22% (127 GW) increase in the year 2020.

Solar energy can help solve one long-existing problem in India: the lack of electricity and clean energy in several parts of the country. India was an early adopter of Solar Technology and recently achieved the 5th global position in solar power deployment by surpassing Italy. Exponential growth can be seen in India’s Solar PV outlook by analyzing data from the International Energy Renewable Agency, since 2011 India has increased its installed solar capacity by 7200% as of 2020 and its electricity generation by 10100% as of December 2018 [3]. [See in Appendix: Graph A & Graph B]

Solar energy is an increasingly important part of India’s current energy mix and will play a vital role in our clean energy future. As per the Ministry of Commerce and Industry, Government of India, the Indian renewable energy sector is the fourth most attractive renewable energy market in the world. As of October 2018, India was positioned fifth in installing a sustainable power source limit. The National Institute of Solar Energy has assessed the country’s solar potential of about 748 GW assuming 3% of the wasteland area to be covered by Solar PV modules, as of 31st March 2021 India only has an installed capacity of 40.1 GW which is 5.4% of it’s potential [1]. The entire solar industry needs to analyze why this technology is not being harnessed to its full potential and that is where understanding the perceptions of the Indian public plays an important role.

Previous literature on domestic PV diffusion has shown that “barriers and enablers tend to go beyond technical and policy advancement” and instead reside at the intersection of “social, economic, and technical context” [4]. The current data points and research in India about Solar Technology do not focus on the ideas of people, the closest possible literature related to the social acceptance of Solar Energy amongst farmers focuses on their risk aversion, business activity, and community trust [5]. Income is a variable with no conclusive evidence in the literature as to how it influences PV adoption [6]. Partially, the failure of these mechanisms and mixed findings in the literature have been attributed to the inability of policymakers and researchers alike in understanding the bandwidth of drivers and inhibitors of the investment decision process and to fit the broader socio-economic context in which they are deployed (Sener et al., 2018; Gimeno et al., 2018) [7]. Innovations such as solar energy spring from urban areas and slowly transition to rural states hence industries must have access to data from urban populations as well. Various other researches point to different socio-economic considerations including “high capital and maintenance costs; limited experience with new energy technology; as well as of under-valuing the long-term benefits of environmental investments [7]. Consumers must also contend with their lack of trust in available information on PV, “uncertainty of the costs associated with operation and maintenance” and “the long timeline for return on investment (ROI)” [8] (Rai and Robinson, 2013; Rai and McAndrews, 2012). Some other studies have shown that due to path dependence of previous carbon-based technology, “consumers must see that the present value of a PV investment greatly exceeds the investment cost by a factor that can surmount consumer uncertainty” (Bauner and Crago, 2015, p. 31). All these fluctuations lead to individual investors going away from the adoption of PV “until market and policy maturity reach a satisfactory level of perceived risk, known as the optional value” (Bauner and Crago, 2015, p. 31).

This research focuses on understanding how the socio-economic background of Indian respondents affects their perception of solar technology. It is believed that richer and economically stable households with less binding budget constraints are more likely to have a positive outlook toward new technology in the form of solar microgrids [5]. Such research holds key importance in the development and implementation of solar technology as it will help governments and firms plan their course of action to achieve high solar electrification rates in the Indian subcontinent.

2. METHODOLOGY

2.1 Aim of the Study

This study aimed to explore how the socio-economic background of respondents affects
their perception of solar technology. This study focuses on understanding and drawing the connections between demographic/economic factors and views of people towards solar technologies. This information is also closely in line with the following United Nations sustainable development goals: Affordable and clean energy, sustainable cities and communities, and climate action.

2.2 Research Design

This research study was mixed-method research that used surveys and secondary data that was collected using various methods such as online and paper-based survey forms, and interviews. The independent variables that were used in the study were the demographic and economic information of the respondents, which included the following: age, level of education, profession, area of residence, and monthly income (both were used to identify the socio-economic background of the respondents). The dependent variables were the awareness and opinion of the respondents about solar technology, and the willingness of the respondents to adopt solar energy in their homes.

2.3 Hypothesis

Null hypothesis 1 - The socioeconomic background of respondents does not affect their perception of new and upcoming technologies such as solar technology.

Alternative hypothesis 1 - The socio-economic background of respondents affects their perception of new and upcoming technologies such as solar technology.

Null hypothesis 2 - There is no relationship between the level of education people have received and the level of awareness they have regarding Solar Technology.

Alternative hypothesis 2 - The level of education of respondents and their awareness of Solar Technology have a direct relationship.

2.4 Sampling and Data Collection

The form consisted of 12 questions that were divided into 2 different sections, Section 1 to collect data relating to the socioeconomic background of the respondents and Section 2 to collect the data corresponding to their perception of solar technology. This form was distributed using social media and online communication platforms, primarily WhatsApp, Facebook, Discord, LinkedIn, and Slack. Forms were also mailed to business personnel to collect data. A total of 110 responses were recorded on this online form.

To collect data from underprivileged groups, an alternative approach of data collection was taken where paper-based forms were made. These forms were designed in Hindi to ensure that they were understood completely by the respondents. The questions were first literally translated from the online paper-based form and then refinements were made to the language and the design of the questions using Google Transliteration. These forms were then checked and compared to the online forms to ensure uniformity and eliminate any sort of bias that might have been generated during translations.

These Paper-based Hindi forms were printed and distributed in the Kishangarh Village, which is mostly populated by domestic help, drivers, small-time shopkeepers, and manual labor. Some of the forms were collected back from the people and some of the forms were filled on the spot in the village. A total of 40 paper-based responses were collected.

3. RESULTS AND DISCUSSION

The data were divided into two groups, one being students and the other one being working professionals. This was done to ensure that the results weren’t skewed due to a difference in the type of respondents. There were 44 total responses in the student’s dataset where 19 responses were from males whereas 25 responses were from females. The gender of the students showed no significant impact on any of the results. When students were asked about their awareness of solar energy on a scale of 1 to 7, the mean of their awareness was recorded at (M = 4.614, SD = 1.185) which was lower than the mean of awareness of working professionals which was recorded a mean of (M = 4.988, SD = 1.637). However, when asked about the benefits of solar energy, the students recorded a higher mean of (M = 6.250, SD = 0.943 ) compared to a mean of (M = 5.588, SD = 1.748 ) for working professionals. The likelihood of adoption for both students and working professionals was almost similar at (M = 5.614, SD = 1.401) and (M = 5.764, SD = 1.315) respectively.
Table 1. Mean values (M) for all dependent variables (awareness of respondents, Degree of perceived benefit, likelihood of adoption) comparing students and working professionals

When asked if they thought solar energy systems will help shape the sustainable future of the Indian economy, 79.5% of students responded with "yes" in agreement with the statement whereas the remaining students were "unsure". On the other hand, 82.3% of working professionals responded with "yes", 14.1% of them were "unsure" and the remaining respondents responded with a "no" saying that solar energy will not be beneficial in shaping a sustainable future of the Indian economy.

Another comparison between students and working professionals was the reasons why they thought solar technology had low adoption rates in India, the respondents were provided with 3 options as well as a blank to fill in their response.

For students, the majority of the respondents believed that high installation and maintenance costs are the key reason for low adoption rates with over 68% of the respondents choosing this option. The data from the student responses can be seen in the pie chart in Fig. 1.

For working professionals, the majority of the respondents believed that High installation and maintenance costs along with a Lack of awareness regarding Solar Technology are the key reasons for low adoption rates. Around 71.4% of respondents chose high installation and maintenance costs and 21.4% chose Lack of awareness as their response.

![Fig. 1. Key driving reason for low solar adoption rates (students)](image_url)
When Respondents were asked to elaborate on their responses to this question most of the responses revolved around a combination of all factors, some examples of elaborate responses are given below:-

3.1 Responses for What People Think is the Driving Reason for the Low Solar Technology Adoption Rates in India?

“Residential flats have limited options for reaping the solar energy in homes (mostly solar panels are being used for hot water) ideally solar panels can also be used for generating electricity for households etc. Also, different states have different regulations (e.g. net metering, etc) when it comes to solar policies ideally there should be some unified policy at the Central level. While solar installations are subsidized, however, there is still a lot of scope for product improvement.”

“Solar technology should be a primary target for the government of the country as to make it available at micro-level with every household & industrial. The Government should announce benefits schemes, like tax benefits, payback, or incentives for lower / middle Social-economic sections of the county so they get encouraged to adapt this technology. At present the infrastructure to get solar technology for home and vehicles are expensive and infrastructure is not readily accessible at the economic level.”

“People are neither aware nor they avoid the hassle, change always needs some time to get adapted. Solar energy should be introduced in our education system right now at all levels. Millennials are more open to new things and they can also be targeted. In any case, the government is mandating it all new constructions so it shall be the essential thing of future, the only challenge left is the old construction and population”.

Table 2. Student responses to “In your view, will Solar Energy systems help shape the sustainable future of the Indian economy?”

When the respondents were asked: “In your view, will Solar Energy systems help shape the sustainable future of the Indian Economy?” Both students and working professionals had similar responses with the majority of respondents choosing “Yes”.

Age: The dataset was then analyzed on the basis of the age of the respondents where data was divided into 4 different categories and means were calculated for responses to different questions. A general upwards trend was seen for Awareness and perceived benefit as the age of respondents increased with an exception in the “Below 18” age bracket. This is likely because the incomes of people are likely to grow as they become more experienced and hence solar energy might become more affordable to them. Age is also likely to have a positive relationship with the likelihood of adoption as older people are more likely to have settled in life and hence would find it easier to take money out from their budget to spend on a solar panel system. For the age bracket under 18 on the other hand, most respondents were students and hence it can be inferred from the data that students have a more positive outlook toward solar energy.

Income: The dataset was then analyzed based on income as an identifying variable, the data for all students were excluded for this variable as none of the students was earning and hence the data would have been skewed as the responses of students and those who are working professionals but don’t earn differ by a high margin. There was a positive correlation between income and the other identification variables that were used to capture the perceptions of respondents with an exception in the “Not earning at the moment” bracket. Further analysis showed that this was because some respondents were perfectly eligible to be employed and had jobs in the past but were either temporarily or willingly unemployed.

Education: The last variable used to analyze the dataset was education level, education level relates directly to the awareness of people about things going around them. Education is closely related to the level of income and self-awareness of happiness. Education is also closely related to economic freedom [9]. This is supported by an analysis of the dataset with education and perception of solar energy having a positive correlation. During the analysis of the dataset with education level as a variable, the data for the students were excluded so that the data was not skewed. The education levels were divided into three different brackets to ensure that the size for all groups was the same and there isn’t any bias while calculating the mean [10].

Three different T-Tests were also conducted between the different education levels out of which two were significant and one was insignificant. The first T-Test was done between the respondents who went to primary and high school and respondents who have a Bachelor's degree. The results of this T-test support the Alternate Hypothesis 2 which states that the level of education of respondents and their awareness regarding Solar Technology has a direct relationship.

The second T-Test was done between the Lowest education level and the Highest education level which were 'Primary and High School' and 'Masters Or Ph.D.' respectively. The results of this T-test support Alternate Hypothesis 2 which states that the level of education of respondents and their awareness regarding Solar Technology has a direct relationship. This relation above also shows that Hypothesis 2 is false.

The third T-Test was done between the Middle education level and the Highest education level which were 'Bachelors Degree' and 'Masters Or Ph.D.' respectively. This T-Test was insignificant as it had a P-value that was greater than 0.05. This shows that there is no significant difference in the level of Awareness between respondents with a bachelor's degree and a Master's or Ph.D. Degree.

4. CONCLUSION

From the results of this study, it can be concluded that both the hypotheses hold true, which are, “The socio-economic background of respondents affects their perception towards new and upcoming technologies such as solar technology” and “The level of education of respondents and their awareness regarding Solar Technology has a direct relationship”. A similar relationship was derived between the likelihood of adoption and the income of the respondents which supports the other hypothesis. The socio-economic background of Indian respondents affects their perception in a way where the people with high-income levels
will have a more positive outlook towards new and upcoming technologies such as solar technology.

Some other findings during this study were that the general trends did not apply to the responses from the students as data from student responses showed that they had a more positive outlook towards solar energy compared to working professionals. The aim of this study has been fulfilled and the data from the study can definitely be used for further research into consumer behavior and sustainable energy.

DISCLAIMER

The products used for this research are commonly and predominantly used in our area of research and country. There is absolutely no conflict of interest between the authors and producers of the products because we do not intend to use these products as an avenue for any litigation but for the advancement of knowledge. Also, the research was not funded by the producing company rather it was funded by personal efforts of the authors.

DECLARATION

The survey was conducted to collect data on the impact of people's socioeconomic background and the effect and how the differences in the same impacted their perception of solar technology. A rather unconventional method was used to collect data as using regular online-based forms would have restricted the audience to only those who have access to the internet. To overcome this problem, two separate methods of data collection were used. The first method was an online google form which was designed in English. Confidentiality and privacy of the respondents were maintained; no data would be disclosed to a third party. No identifiers such as names or pictures were disclosed in the article or while conducting the study. Ethical guidelines of research were followed.

CONSENT

As per international standard or university standard, respondents’ written consent has been collected and preserved by the author(s).

ACKNOWLEDGEMENT

I would like to thank my research mentors who helped me understand the process of writing a research paper and guided me at each step of writing this paper. I would also like to thank my teachers both in and outside the school who helped me in deciding topics for the study as well as proofreading sections of the paper: Ashima ma’am, Geeta ma’am and Uttamesh sir. A special thanks to my house helping staff, Mr Manoj Shaw, who helped me distribute the paper-based forms in Kishangarh.

COMPETING INTERESTS

Author has declared that no competing interests exist.

Impact of socio-economic background on Solar Energy in India

Dear Invitee,

My name is Viraj Malik and I am a high school student in New Delhi. I am kindly requesting your participation in a research that I am conducting on the economics behind Solar Technology in India. The intention of this study is to assess how the Socio-economic background of Indian respondents affects their perception towards Solar Energy.

The study is completely anonymous and does not require you to provide your name or any other identifying information. Your participation in the research will be very valuable in exploring the future of Solar Energy in India, which will provide a base for government authorities and Industrial firms to analyse and plan the upcoming few years of Solar development in our nation.

Thank you for your time and participation.

Regards,
Viraj Malik
